High dose intravenous (IV) ascorbic acid (AA) has been used as therapy for infectious disease from bacterial and viral origin and adjuvant therapy for cancer. In this publication we describe a clinical protocol that has been developed over the past twenty years utilizing high dose IVAA as therapy for cancer. This includes principles of treatment, rationale, baseline workup, infusion protocol, precautions and side effects.

Key words: Intravenous ascorbic acid, Intravenous vitamin C, Cancer

High dose intravenous ascorbic acid (IAA) has been used as a therapy for bacterial infection, viral infection, and as adjuvant therapy for Cancer (1-7). The treatment rationale for the use of IAA in treatment of cancer has been described in detail elsewhere (7-9). In general cancer patients have depressed circulatory, cellular and tissue ascorbate levels and reserves. Ascorbate administered in pharmacological doses enhances various parameters associated with better prognosis (7-8). There is also evidence that physiologically attainable concentrations by intravenous administration are selectively toxic to cancer cells (3-7,10); contrary to the limited levels of ascorbate that can be reached by oral intakes. Moreover, there is evidence of synergism between the conventional methods for cancer treatment (surgery, radiation and chemotherapy) when utilized with ascorbate (11-13).

Principle of Treatment

Over 21 years of clinical experience using intravenous ascorbate in cancer patients indicate that the best responses are obtained when maintaining a continuous high plasma ascorbate level (3-7,10,14). Initially, doses of 15g per infusion were used, once or twice per week. These doses improved patient’s sense of well being, reduced pain and in many cases improved survival times beyond predictions of experienced oncologists. Later using 30 grams of IAA, twice per week, it was found that metastatic lesions in lung and liver of a man with primary renal cell carcinoma disappeared in a matter of weeks (3). At the time it was believed that IAA was helpful to cancer patients solely through two mechanisms: by increasing production and strengthening extra cellular collagen (in this manner preventing metastasis and further tumor growth) and by improving immune function (immune cell’s activity and interferon). Subsequently, resolution of bone metastases in a patient with primary breast cancer was reported using infusions of 100 grams once or twice per week (4). Now it is known that other mechanism(s) exists by which ascorbic acid (AA) and its salts are capable of cytotoxic activity against malignant tissue. AA is preferentially toxic to tumor cells (5), this preferential toxicity has been detected in multiple tumor cell types in vitro (14).

Also, plasma concentrations of AA required for killing tumor cells have been achieved in humans (5,10). Others have described in vivo toxicity of AA in multiple tumor types and in animal models, even in animals bearing human tumors (15-20).

Treatment Rationale

From previous studies (4,10,14), we concluded that:

- tumor cells are more susceptible to high dose ascorbate induced peroxidation products (mainly H₂O₂) due to their relative deficiencies in antioxidant enzymes, mainly catalase and superoxide dismutase;
- concentrations of ascorbate high enough to kill tumor cells can be achieved in humans by IAA administration.
Samples of human serum from patients receiving IAA confirmed that AA concentrations in vivo can reach levels that are cytotoxic to tumor cells in vitro. Using densely populated monolayers, a three-dimensional hollow fiber tumor model with the use of human serum as a growth medium to closely mimic the in-vitro environment it was found that an AA plasma concentration of 400 mg/dL effectively kills tumor cell types (14). Earlier it was reported that 40 mg/dL of plasma AA was adequate to kill tumor cells but this data was generated from in-vitro studies utilizing sparsely populated cell monolayers and standard tissue culture medium. Interestingly, human serum has been reported to decrease ascorbic acid cytotoxicity in cancer cells (10). This action is probably due to its antioxidant capacity. IAA is actually an off-label treatment, therefore, an appropriate informed consent must be read, understood and signed by the patient.

As with any cancer treatment it is important to establish certain baseline data before starting treatment, in order to monitor future therapeutic response. Such baseline data may vary depending upon the type and extent of the particular cancer of the patient being treated. It is necessary to include the patients weight, full hematological profile, SMAC-20 profile, G6PD test, measurement of serum tumor marker proteins if present and clinical and radiological measurements (CAT-Scan, MRI if appropriate) and, if possible, a performance on the Karnovsky scale.

Precautions and side effects. The side effects of IAA are rare. However, there are contraindications and potential side effects that should be considered. Although it has only been reported once in the literature, tumor necrosis, hemorrhage and subsequent death after a single intravenous 10 gm dose of ascorbic acid, as reported by Campbell and Jack (21), should be the highest concern for the safety of IAA in cancer patients; for this reason, it is advisable to begin with a small dose. Patients with highly anaplastic, rapid growing tumors with heavy tumor load should be carefully monitored.

Clinically those patients will present sudden pain in the areas of tumor deposit, swelling, tumor hemorrhage (internal and external), hyperpyrexia, severe hypertension, tachycardia and azotemia (2). This extremely rare complication can be fatal and must be vigorously treated. If suspected, the ascorbate infusion should be immediately discontinued and the patient treated as for septic shock. It has been reported that after such event, residual tumor has considerably decreased in size or even disappeared. (2,21). Although, highly dangerous, this reaction might also be termed as the best possible response to ascorbate treatment of widespread malignancy.

Another report describes acute oxalate nephropathy in a patient with bilateral ureteric obstruction and renal insufficiency who received 60 gram IAA's (22); there is also a report of a patient with colon carcinoma, receiving daily IAA, who developed nausea and vomiting requiring hospitalization for dehydration (Hanson J, personal communication). Both of these cases show the need to assess the patient's renal function, hydration status and voiding capacity.

Although rare, hemolysis can occur in patients with glucose 6-phosphate dehydrogenase (G6PD) deficiency, due to its oxidative capacity and increased formation of hydrogen peroxide (23,24). Localized pain and stinging sensation at the infusion site can occur if the infusion rate is too fast or 0.9% NaCl is used as a carrier solution. Dextrose should never be used as a carrier solution since glucose may stimulate tumor growth by enhancing glycolysis. Since ascorbate may work as a chelating agent, some individuals may experience tremors due to hypocalcemia.

Rivers (25) reported that high dose IAA is contraindicated in renal insufficiency, chronic hemodialysis patients, unusual forms of iron overload and oxalate stone formers. However, two reports (26,27) show that magnesium oxide (300mg/d, orally) and vitamin B6 (10mg/d, orally) inhibit oxalate stone formation in recurrent stone formers and can be provided to the patients. Given the amount of fluid which is used as a vehicle for the ascorbate and the sodium hydroxide/sodium bicarbonate used to adjust the pH, any condition which can be adversely affected by increased fluid or sodium such as: congestive heart failure, ascites, edema, hypertension, is relatively contraindicated. Ascorbate is preferably given by intravenous drip. It should never be given IV push as the osmolality of high doses are capable of sclerosing peripheral veins. An IV fluid osmolality of less than 1,200 mOsm will be tolerated well by most patients. (Table 1)

Infusion solution. In high dose ascorbate therapy many intravenous solutions are hypertonic. This does not seem to present a problem as long as the infusion rate is low enough and the toxicity does not exceed 1,200 mOsm (mOsm). When infusing AA it should be mixed with Ringer’s lactate (RL) solution when of up to 25 grams and/or sterile water for larger amounts. We recommended the use of sodium ascorbate/ascorbic acid mixture containing 0.91 mols of sodium per mols of ascorbate (500 mg AA/mL, pH range 5.5-7.0, Merit Pharmaceuticals, Los Angeles, California, Maelkaskey Pharmaceuticals, Wichita, Kansas, Bioniche Pharm, London, Ontario, Canada.) Table 1 shows the osmolalities of commonly prepared solutions and Table 2 shows the final volume to maintain normal osmolality.

Infusion. As indicated in the precautions, a small starting dose of 15gm AA in 250ml RL over 1hr is recommended and the patient is observed closely for any adverse event.
Table 1. Osmolarity of various amounts of sodium ascorbate/ascorbic acid in sterile water and Ringer’s Lactate (mOsm; isotonic = 300 mOsm). Hypotonic solutions are underlined; useful solutions from isotonic to 1200 mOsm are in bold. An equal volume of IV solution is removed from the bag or bottle, prior to adding concentrated sodium ascorbate/ascorbic acid solution (500mg/mL).

Remainder to subtract AA quantity from bag or fluid.

The dose can be gradually increased over time but the infusion rate should not exceed 1 gm AA per min., 0.5 gm/min is well tolerated by most patients. Although there is variability due to scheduling and tolerance, a typical protocol may consist of the following infusions:

- Week 1: 1 x 15gm. infusion per day 2-3 per week
- Week 2: 1 x 30gm. infusion per day 2-3 per week
- Week 3: 1 x 65gm. infusion per day 2-3 per week
- Week 4: 1 x 100gm. infusion per day 2-3 per week

The dose is then adjusted to achieve transient plasma concentrations of 400mg/dL, 2-3 infusions per week or 200 mg/dL if taking oral lipoic acid (300 mg bid). This protocol should be followed for at least a year. The goal of the infusions is to raise plasma ascorbate concentration above cytotoxic levels for tumor cells as long as possible. The AA molecule is very similar to glucose, which greatly facilitates its entrance into the malignant cell. Because the ascorbate is so readily cleared by the kidney, the optimal infusion rate will result in tumor cytotoxic plasma levels of ascorbate for the largest periods of time and hopefully, maximum tumor cell lysis. Patients are advised to supplement orally with at least 5 gm. daily when no infusion is given, in order to maintain basal tissue levels and prevent a rare, but possible scurvy rebound effect.

Resumen

El ácido ascorbico (AA) en altas dosis intravenosas (IV) ha sido utilizado como terapia para enfermedades infecciosas de origen bacteriano y viral, así como terapia adyuvante contra cancer. En esta publicación describimos un protocolo clínico que ha sido desarrollado durante los pasados veinte años utilizando AA en altas dosis IV como terapia para cancer. Este trabajo incluye principios de tratamiento, fundamentos científicos, laboratorios y pruebas iniciales, protocolo de infusión y efectos secundarios.
